# Nokia 6100 LCD Display Driver

**Revision 1** 

Author:

James P. Lynch

# Introduction

There have been countless millions of Nokia cell phones sold world-wide and this economy of scale has made it possible for the hobbyist and experimenter to procure the LCD graphic display from these phones at a reasonable price. Sparkfun Electronics (<u>www.sparkfun.com</u>) sells a model 6100 for \$19.95 (US). I've seen sources for this display on EBay for \$7.99 (US) plus \$10.00 shipping (from Hong Kong, so shipping is a bit slow). The Swedish web shop Jelu (<u>www.jelu.se</u>) has this display for about \$20.00 (US) also (see photograph below).

Olimex uses these displays on their more sophisticated development boards, so this tutorial will be geared to the Olimex SAM7-EX256 board shown on the front cover.

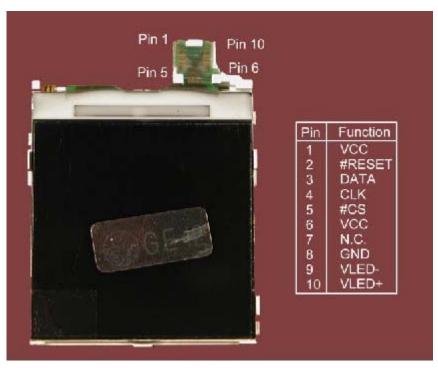

Figure 1. Nokia 6100 LCD Display (from Jelu web site)

The important specifications for this display are as follows:

132 x 132 pixels12-bit color rendition (4 bits red, 4-bits green, 4-bits blue)3.3 volts9-bit SPI serial interface (clock/data signals)

The major irritant in using this display is identifying the graphics controller; there are two possibilities (Epson S1D15G00 or Philips PCF8833). The LCD display sold by the German Web Shop Jelu has a Leadis LDS176 controller but it is 100% compatible with the Philips PCF8833). So how do you tell which controller you have? Some message boards have suggested that the LCD display be disassembled and the controller chip measured with a digital caliper – well that's getting a bit extreme.

Here's what I know. The Olimex boards have both display controllers possible; if the LCD has a GE-12 sticker on it, it's a Philips PCF8833. If it has a GE-8 sticker, it's an Epson controller. The older Sparkfun 6100 displays were Epson, their web site indicates that the newer ones are an Epson clone. Sparkfun software examples sometimes refer to the Philips controller so the whole issue has become a bit murky. The trading companies in Honk Kong have no idea what is inside the displays they are selling. A Nokia 6100 display that I purchased from Hong Kong a couple of weeks ago had the Philips controller. I was not happy with any of the driver software examples I had inspected; they all seemed to be "mash-ups" – collections of code snippets for both types of controllers mixed together. None of these examples matched exactly the Philips PCF8833 or the Epson S1D15G00 user manuals, which can be downloaded from these links.

Philips/NXP PCF8833: http://www.nxp.com/acrobat\_download/datasheets/PCF8833\_1.pdf

Epson S1D15G00: <u>http://www.sparkfun.com/commerce/product\_info.php?products\_id=569</u>

So I set out to write a driver based solely on the LCD controller manufacturer's manual. This is not to say that I didn't have my own mysteries. I had to "invert" the entire display and "reverse" the RGB order to get the colors to work out properly for the Philips controller. The Epson S1D15G00 user manual is a poor English translation and nearly incomprehensible.

To keep this tutorial simple, I will not address the issues of scrolling or partial displays (to conserve power) since these are rarely-used features.

I used the Olimex SAM7-EX256 evaluation board as the execution platform. This is an ARM7 board with many peripherals that is an excellent way to learn about the ARM architecture at a reasonable price (\$120 from Sparkfun). I also used the YAGARTO/Eclipse platform as the cross-development environment which is explained in great detail in my tutorial "Using Open Source Tools for AT91SAM7 Cross Development" which can be downloaded from the following link:

http://www.atmel.com/dyn/resources/prod\_documents/atmel\_tutorial\_source.zip

Hardware connection issues are also not the subject of this tutorial; you can download the Olimex schematic for the SAM7-EX256 board to see their design for a hardware interface to the Nokia 6100 LCD display.

# **LCD Display Orientation**

The Nokia 6100 display has 132 x 132 pixels; each one with 12-bit color (4 bits RED, 4 bits GREEN and 4 bits BLUE). Practically speaking, you cannot see the first and last row and columns. The normal orientation is as follows:

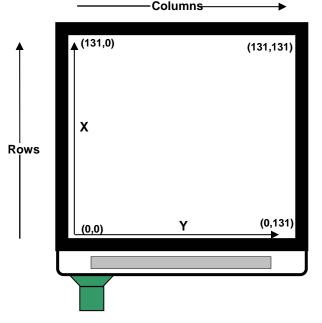

Figure 2. Default Orientation of Nokia 6100 LCD Display

That, of course, is upside-down on the Olimex SAM7-EX256 board if the silk-screen lettering is used as the up/down reference. So I set the "mirror x" and "mirror y" command to rotate the display 180 degrees, as shown below. This will be the orientation used in this tutorial (it is so easy to change back, if you desire).

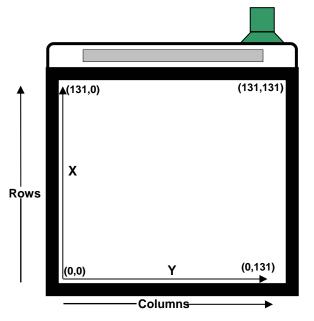

Figure 3. Tutorial Orientation of Nokia 6100 LCD Display

# **Communication with the Display**

The Nokia 6100 uses a two-wire serial SPI interface (clock and data). The ARM7 microcontroller SPI peripheral generates the clock and data signals and the display acts solely as a slave device. Olimex elected to not implement the MISO0 signal that would allow the ARM microcontroller to read from the LCD display (you could read some identification codes, status, temperature data, etc). Therefore, the display is strictly **write-only**!

We send 9 bits to the display serially, the ninth bit indicates if a command byte or a data byte is being transmitted. Note in the timing diagram below from the Philips manual, the ninth bit (command or data) is clocked out first and is LOW to indicate a command byte or HIGH to indicate a data byte.

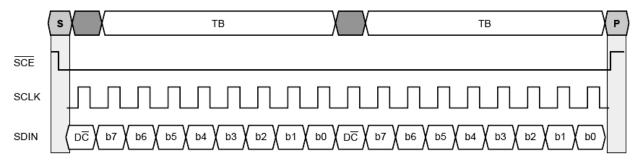

Figure 4. SPI serial interface sends commands and data bytes

How fast can this SPI interface be run? Since the PCF8833 data sheet specifies that the serial clock SCLK period be no less than 150 nsec, dividing the board's master clock (48054841 Hz) by 8 gives a period of 166 nsec. Thus we can safely run the SPI interface at 6 MHz. I have run the SPI interface at 16 MHz and it still worked, but that is tempting fate.

The SAM7-EX256 board uses an ARM7 microprocessor; so commands or data are submitted to the SPI peripheral as unsigned integers (32 bits) wherein only the lower 9 bits are used.

For example, to send a command we **clear** bit 8 to specify this is a command transmission. The lowest 8 bits contain the desired PCF8833 command.

unsigned int	command;	// PCF8833 command byte
	_SR & AT91C_SPI_TXEMPTY) == 0); nand & (~0x0100)); command;	// wait for the previous transfer to complete // clear bit 8 - indicates a "command" byte // send the command

Likewise, to send a data byte we **set** bit 8 to specify that this is a data transmission. The lowest 8 bits contain the desired PCF8833 data byte.

unsigned int	data;	// PCF8833 data byte
while ((pSPI->SPI data = (data   0x01 pSPI->SPI_TDR =		// wait for the previous transfer to complete // set bit 8 - indicates a "data" byte // send the command

Both snippets have a "wait until TXEMPTY" to guarantee that a new command/data stream is not started before the previous one has completed. This is quite safe as you will never get stuck forever in that wait loop.

The LCD driver has three functions supporting the SPI interface to the LCD:

InitSpi()	- sets up the SPI interface #1 to communicate with the LCD
WriteSpiCommand(command)	- sends a command byte to the LCD
WriteSpiData(data)	- sends a data byte to the LCD

Using these commands is quite simple; for example, to initialize the SPI interface and then set the contrast for the Philips controller:

InitSpi();	// Initialize SPI interface to LCD
WriteSpiCommand(SETCON);	<pre>// Write contrast (command 0x25)</pre>
WriteSpiData(0x30);	// contrast $0x30$ (range is -63 to +63)

The hardware interface uses five I/O port pins; four bits from PIOA and one bit from PIOB, as shown in Table 1 and Figure 5 below.

PA2	LCD Reset (set to low to reset)
PA12	LCD chip select (set to low to select the LCD chip)
PA16	SPI0_MISO Master In - Slave Out (not used in LCD interface)
PA17	SPI0_MOSI Master Out - Slave In pin (Serial Data to LCD slave)
PA18	SPI0_SPCK Serial Clock (to LCD slave)
PB20	backlight control (normally PWM control, 1 = full on)

Table 1. I/O port bits used to support the SPI interface to the LCD Display

Note in Table 1 above that Olimex elected not to support the SPIO\_MOSI – Master In bit (PA16) which would have allowed the user to read from the display. The LED backlight needs a lot of current, so a 7-volt boost converter is used for this purpose. The backlight can be turned on and off using PB20. It looks like you might be able to PWM the backlight, but I doubt anyone would want the backlight to be at half brightness.

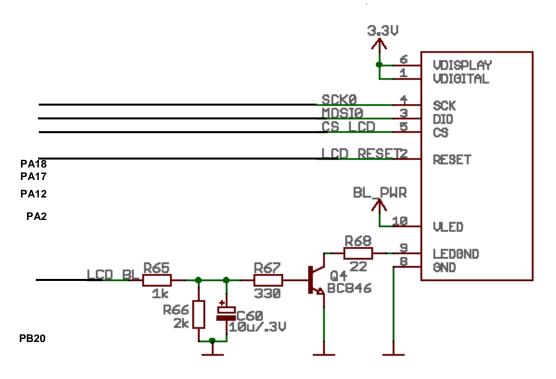

Figure 5. Hardware Interface to Nokia 6100 LCD Display (Olimex design)

# **Addressing Pixel Memory**

The Philips PCF8833 controller has a 17424 word memory (132 x 132), where each word is 12 bits (4-bit color each for red, green and blue). You address it by specifying the address of the desired pixel with the Page Address Set command (rows) and the Column Address Set command (columns).

The Page Address Set and Column Address Set command specify two things, the starting pixel and the ending pixel. This has the effect of creating a drawing box. This sounds overly complex, but it has a wrap-around and auto-increment feature that greatly simplifies writing character fonts and filling rectangles.

The pixel memory has 132 rows and 132 columns, as shown below in Figure 6

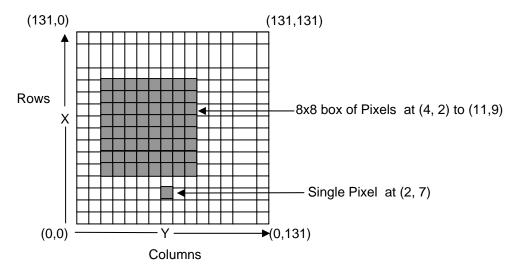

Figure 6. Philips PCF8833 Pixel Memory

To address a single pixel, just specify the same location for the starting pixel and the ending pixel on each axis. For example, to specify a single pixel at (2, 7) use the following sequence.

WriteSpiCommand(PASET);	// Row address set (command 0x2B)
WriteSpiData(2);	// starting x address
WriteSpiData(2);	// ending x address (same as start)
WriteSpiCommand(CASET);	// Column address set (command 0x2A)
WriteSpiData(7);	// starting y address
WriteSpiData(7);	// ending y address (same as start)

To address a rectangular area of pixels, just specify the starting location and the ending location on each axis, as shown below. For example, to define a drawing rectangle from (4, 3) to (11, 9) use the following sequence.

WriteSpiCommand(PASET);	// Row address set (command 0x2B)
WriteSpiData(4);	// starting x address
WriteSpiData(11);	// ending x address
WriteSpiCommand(CASET);	// Column address set (command 0x2A)
WriteSpiData(3);	// starting y address
WriteSpiData(9);	// ending y address

Once the drawing boundaries have been established (either a single pixel or a rectangular group of pixels), any subsequent memory operations are confined to that boundary. For instance, if you try to write more pixels than defined by the boundaries, the extra pixels are discarded by the controller. The Epson S1D15G00 controller has essentially the same memory layout as the Philips/NXP PCF8833.

## **12-Bit Color Data**

The Philips PCF8833 LCD controller has three different ways to specify a pixel's color.

#### 1. **12 bits per pixel** (native mode)

Selection of the native 12 bits/pixel mode is accomplished by sending the Color Interface Pixel Format command (0x3A) followed by a single data byte containing the value 3.

This encoding requires a Memory Write command and 1.5 subsequent data bytes to specify a single pixel. The bytes are packed so that two pixels will occupy three sequential bytes and the process repeats until the drawing boundaries are used up. Figure 7 illustrates the 12 bits/pixel encoding.

0	0	1	0	1	1	0	0	RAMWR command (memory write)
R	R	R	R	G	G	G	G	Data: Red and green from 1 <sup>st</sup> pixel
В	В	В	В	R	R	R	R	Data: Blue from 1 <sup>st</sup> pixel; red from 2 <sup>nd</sup> pixel
G	G	G	G	В	В	В	В	Data: Green and blue from 2 <sup>nd</sup> pixel

Figure 7. Color encoding for 12 bits / pixel - example illustrates sending 2 pixels

You might pose the question "What happens if I specify a single pixel with just two data bytes. Will the 4-bits of red information from the next pixel (usually set to zero) perturb the neighboring pixel? The answer is no since the PCF8833 controller writes to display RAM only when it gets a complete pixel. The straggler red bits from the next pixel wait for the completion of the remaining colors which will never

come. Appearance of any command will cancel the previous memory operation and discard the unused pixel information. To be safe, I added a NOP command in the LCDSetPixel() function to guarantee that the unused red information from the next pixel is discarded.

Figure 8 demonstrates how to send a single pixel using 12-bit encoding. Note that the last 4 red bits from the next pixel will be ignored.

0	0	1	0	1	1	0	0	RAMWR command (memory write)
R	R	R	R	G	G	G	G	Data: Red and green from 1 <sup>st</sup> pixel
В	В	В	В	0	0	0	0	Data: Blue from 1 <sup>st</sup> pixel; set red from 2 <sup>nd</sup> pixel to zero
0	0	0	0	0	0	0	0	NOP command (no operation)
								This "red" pixel information for the next pixel will be discarded by the NOP command that follows!

Figure 8. Color encoding for 12 bits / pixel - example illustrates sending 1pixel

#### 2. 8 bits per pixel

Selection of the reduced resolution 8 bits/pixel mode is accomplished by sending the Color Interface Pixel Format command (0x3A) followed by a single data byte containing the value 2.

This encoding requires a Memory Write command and a single subsequent data byte to specify a single pixel. The data byte contains all the color information for one pixel. The color information is encoded as 3 bits for red, 3 bits for green and 2 bits for blue, as shown in Figure 9 below

0	0	1	0	1	1	0	0
R	R	R	G	G	G	В	В

RAMWR command (memory write)

Data: Red, green, and blue encoding - 8 bits/pixel

Figure 9. Color encoding for 8 bits – per - pixel

The important thing to note here is that this 8-bit color encoding will be converted to the 12-bit encoding by the Color Table that you set up in advance. This Color Set table will convert 3-bit RED to 4-bit RED, 3-bit GREEN to 4-bit GREEN and 2-bit BLUE to 4-bit BLUE. This is made possible by the specification of the 20 entry color table in the initialization step.

WriteSpiCommand(RGBSET);	// Define Color Table (command 0x2D)
WriteSpiData(0);	// red 000 value
WriteSpiData(2);	// red 001 value
WriteSpiData(5);	// red 010 value
WriteSpiData(7);	// red 011 value
WriteSpiData(9);	// red 100 value
WriteSpiData(11);	// red 101 value
WriteSpiData(14);	// red 110 value
WriteSpiData(16);	// red 111 value
WriteSpiData(0);	// green 000 value
WriteSpiData(2);	// green 001 value
WriteSpiData(5);	// green 010 value
WriteSpiData(7);	// green 011 value
WriteSpiData(9);	// green 100 value
WriteSpiData(11);	// green 101 value
WriteSpiData(14);	// green 110 value
WriteSpiData(16);	// green 111 value
WriteSpiData(0);	// blue 000 value
WriteSpiData(6);	// blue 001 value
WriteSpiData(11);	// blue 010 value
WriteSpiData(15);	// blue 011 value

Consider the following points. The resolution of the Nokia 6100 display is 132 x 132 pixels, 12 bits/pixel. Since the 8 bits/pixel encoding is converted by the color table to 12 bits/pixel, there is no saving of display memory. The 8 bits/pixel encoding would use about 1/3 less data bytes to fill an area, so there would be a performance gain in terms of the number of bytes transferred. The 8 bits/pixel encoding would make a photograph look terrible. In the author's view, there's very little to be gained by using this mode in an ARM microcontroller environment. Therefore, I elected to not implement the color table and 8-bit encoding in this driver.

#### 3. 16 bits per pixel

Selection of 16 bits/pixel mode is accomplished by sending the Color Interface Pixel Format command (0x3A) followed by a single data byte containing the value 5.

This encoding requires a Memory Write command and two subsequent data bytes to specify a single pixel. The color information is encoded as 5 bits for RED, 6 bits for GREEN and 5 bits for BLUE, as shown in Figure 10 below

0	0	1	0	1	1	0	0
R	R	R	R	R	G	G	G
G	G	G	В	В	В	В	В

RAMWR command (memory write)

Data: Red (5 bits), Green (6 bits)

Data: Green (6 bits), Blue (5 bits)

Figure10. Color encoding for 16 bits - per - pixel

This pixel encoding is converted by the controller using a dithering technique to the 12-bit data for the pixel RAM. The net effect is to give 65k color variations. My view is that nobody is going to display the Mona Lisa on this tiny display, so 16-bit color encoding would be rarely used. I did not include support for it in the driver software, but you could easily add it if you desire. The Epson S1D15G00 controller supports the 8-bit and 12-bit modes, but not the 16-bit mode.

## **Wrap-Around and Auto Increment**

The wrap-around feature is the cornerstone of the controller's design and it amazes me how many people ignored it in drawing rectangles and character fonts. This feature allows you to efficiently draw a character or fill a box with just a simple loop – taking advantage of the wrap-around after writing the pixel in the last column and auto-incrementing to the next row. Remember how the pixel was addressed by defining a "drawing box"? If you are planning to draw an 8 x 8 character font, define the drawing box as 8 x 8 and do a simple loop on 64 successive pixels. The row and column addresses will automatically increment and wrap back when you come to the end of a row, as shown in Figure 11 below.

The rules for Auto-incrementing and Wrap-Around are as follows.

- Set the column and row address to the bottom left of the drawing box.
- Set up a loop to do all the pixels in the box. Specifically, since three data bytes will specify the color for two pixels, the loop will typically iterate over ½ the total number of pixels in the box.
- Writing three memory bytes will illuminate two pixels (12-bit resolution). Each pixel written automatically
  advances the column address. When the "max" column address pixel is done, the column address
  wraps back to the column starting address AND the row address increments by one. Now keep writing
  memory bytes until the next row is illuminated and so on.

Figure 11 shows the traversal of the drawing box.

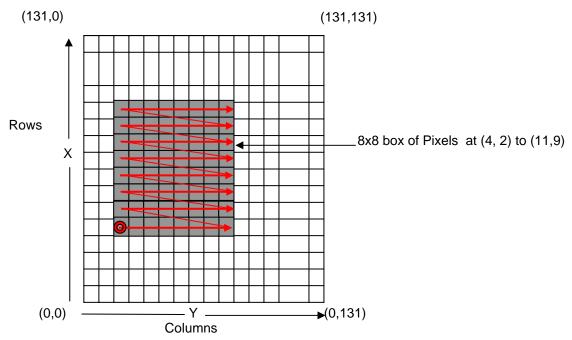

Figure 11. Drawing Box permits auto-increment and wrap-around.

To illustrate this technique, Figure 12 shows the code to fill an 8 x 8 box shown above. Note that we set the row and column address just once (pointing to the lower left corner). Then we do a single Memory Write command followed by three data bytes done 33 times. The grand total is 106 SPI transmissions.

Compare that to the implementation where you address each pixel, set Memory Write and feed two bytes of color data for each pixel. The grand total would be 576 SPI transmissions. The advantage gained using the auto-increment and wrap-around features is obvious.

```
// Row address set (command 0x2B)
WriteSpiCommand(PASET);
WriteSpiData(4);
WriteSpiData(11);
// Column address set (command 0x2A)
WriteSpiCommand(CASET);
WriteSpiData(2);
WriteSpiData(9);
                                                    Add one to account
// Write Memory (command 0x2C)
                                                    for possible round-off
WriteSpiCommand(RAMWR);
                                                    error in the divide by 2
// loop on total number of pixels / 2
for (i = 0; i < ((((11 - 4 + 1) * (9 - 2 + 1)) / 2) + 1); i++) {
        // use the color value to output three data bytes covering two pixels
        WriteSpiData((color >> 4) & 0xFF);
        WriteSpiData(((color & 0xF) << 4) | ((color >> 8) & 0xF));
        WriteSpiData(color & 0xFF);
}
```

Code to use this technique to draw a character font is similar, but at each pixel you have to determine if the font calls for a foreground color or the background color.

# Initializing the LCD Display (Philips PCF8833)

This was a surprise to me but the Philips PCF8833 does not quite boot into a "ready to display" mode after hardware reset. The following is the minimal commands/data needed to place it into 12-bit color mode.

First, we do a hardware reset with a simple manipulation of the port pin. Reset is asserted low on this controller.

// Hardware reset LCD\_RESET\_LOW; Delay(20000); LCD\_RESET\_HIGH; Delay(20000);

The controller boots into SLEEPIN mode, which keeps the booster circuits off. We need to exit sleep mode which will also turn on all the voltage booster circuits.

// Sleep out (command 0x11)
WriteSpiCommand(SLEEPOUT);

This is still a mystery to me, but I had to invert the display and reverse the RGB setting to get the colors to work correctly in this particular display. If you have trouble, consider removing this command.

// Inversion on (command 0x20)
WriteSpiCommand(INVON); // seems to be required for this controller

For this driver, I elected to use the 12-bit color pixel format exclusively.

In setting up the memory access controller, I elected to use the "mirror x" and "mirror y" commands to reorient the x and y axes to agree with the silk screen lettering on the Olimex board. If you want the default orientation, send the data byte 0x08 instead. Finally, I had to reverse the RGB color setting to get the color information to work properly. You may want to experiment with this setting.

// Memory access controller (command 0x36).
WriteSpiCommand(MADCTL);
WriteSpiData(0xC8); // 0xC0 = mirror x and y, reverse rgb

I found that setting the contrast varies from display to display. You may want to try several different contrast data values and observe the results on your display.

// Write contrast (command 0x25)
WriteSpiCommand(SETCON);
WriteSpiData(0x30); // contrast 0x30
Delay(2000);

Now that the display is initialized properly, we can turn on the display and we're ready to start producing characters and graphics.

// Display On (command 0x29)
WriteSpiCommand(DISPON);

# Initializing the LCD Display (Epson S1D15G00)

The Epson S1D15G00 controller also does not quite boot into a "ready to display" mode after hardware reset. The following is the minimal commands/data needed to place it into 12-bit color mode.

First, we do a hardware reset with a simple manipulation of the port pin. Reset is asserted low on this controller.

// Hardware reset LCD\_RESET\_LOW; Delay(20000); LCD\_RESET\_HIGH; Delay(20000);

Display timing is left at the default (P1 = 0), the duty setting is based on 132 lines (P2 = 0x20) and there will be no inversely highlighted lines (P3 = 0).

// Display control
WriteSpiCommand(DISCTL);
WriteSpiData(0x00); // P1: 0x00 = 2 divisions, switching period=8 (default)
WriteSpiData(0x20); // P2: 0x20 = nlines/4 - 1 = 132/4 - 1 = 32)
WriteSpiData(0x00); // P3: 0x00 = no inversely highlighted lines

To be completely honest here, the common output scan direction chosen below (P1 = 1) is the only setting I found by experiment that resulted in a normal display; all other settings resulted in split-displays.

// COM scan WriteSpiCommand(COMSCN); WriteSpiData(0x01); // P1: 0x01 = Scan 1->80, 160<-81

Since the Epson S1D15G00 boots up with the oscillators off and in sleep mode, we have to turn the oscillators on and get out of sleep mode.

// Internal oscilator ON
WriteSpiCommand(OSCON);

// Sleep out
WriteSpiCommand(SLPOUT);

Now turn on all the voltage regulators.

// Power control
WriteSpiCommand(PWRCTR);
WriteSpiData(0x0f); // reference voltage regulator on, circuit voltage follower on, BOOST ON

Just like the Philips PCF8833 controller, you have to "invert" the display to make the colors display correctly.

// Inverse display
WriteSpiCommand(DISINV);

The DATCTL command selects the display mode (8-bit or 12-bit). I selected "16 gray-scale" display (P3 = 2) which forces 12-bit color just like the Philips example earlier. The RGB sequence was left as the default value (P2 = 0) and finally I selected page address inverted, column address normal and address scan in the column direction (P1 = 1). I was unable to get the display to work properly in the "default" orientation (connector bottom left) so this initialization assumes that the display is mounted with the connector top right.

// Data control
WriteSpiCommand(DATCTL);
WriteSpiData(0x01); // P1: 0x01 = page address inverted, col address normal, address scan in col direction
WriteSpiData(0x00); // P2: 0x00 = RGB sequence (default value)
WriteSpiData(0x02); // P3: 0x02 = Grayscale -> 16 (selects 12-bit color, type A)

The contrast is set by the Electronic Volume Command (VOLCTR). The resistance ratio was set to 3 by experiment; this being the only value that worked. The setting of the volume (contrast) value was also determined by experiment. You should try several values to find the one that yields the most pleasing contrast for your display.

// Voltage control (cont	U/	
WriteSpiCommand(VO	LCTR);	
WriteSpiData(32);	// P1 = 32	volume value (adjust this setting for your display 063)
WriteSpiData(3);	// P2 = 3	resistance ratio (determined by experiment)

Finally, delay a bit to allow the power regulator circuits to stabilize and then turn on the display. This delay period is crucial; a fact determined by experiment.

// allow power supply to stabilize
Delay(100000);

// turn on the display
WriteSpiCommand(DISON);

# **Description of the Software Modules**

The driver consists of a C module (**Icd.c**) and a compatible H file (**Icd.h**). There is one version of each for the Philips PCF8833 controller and another version of each for the Epson S1G15D00 controller. The main program runs a series of texts to demonstrate the capabilities of the driver.

A printout of the LCD driver code (both versions) and a simple main program to test it follows directly below. Suitable Eclipse CDT projects are also available in zip file format for those who have the Olimex board.

### LCD.H (for Philips PCF8833 Controller only)

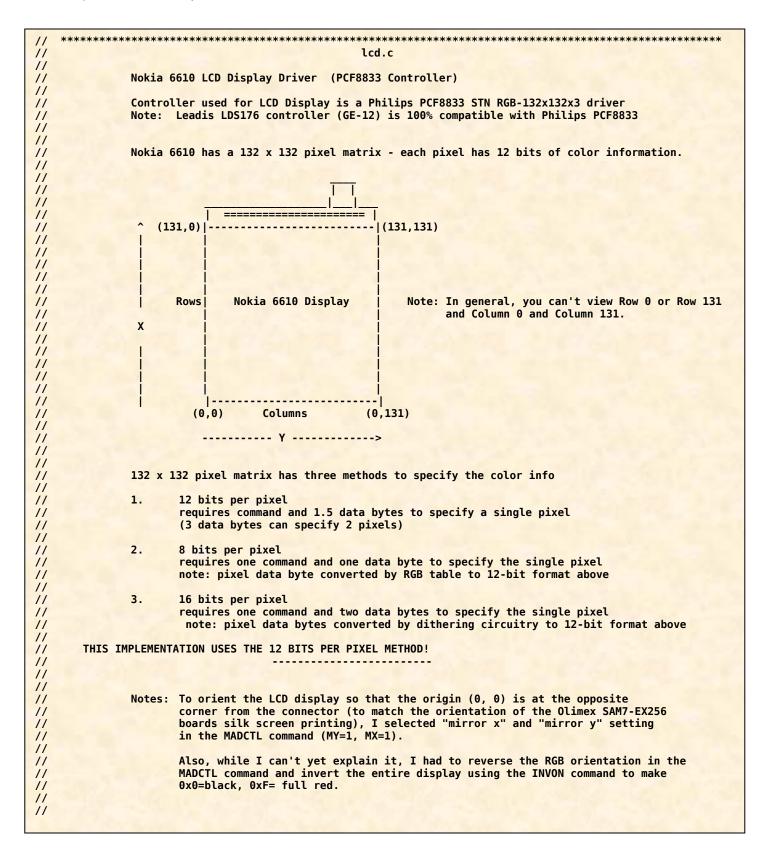

The Icd.h include file contains the Philips commands and color specification codes.

### LCD.C (for Philips PCF8833 Controller only)

The **Icd.c** module contains the SPI support code and a complete set of LCD graphics primitives. The line drawing and circle routines are derived from the famous Jack Bresenham algorithms from 1962. The rest of the graphics primitives are designed by the author. The font tables were adapted from the ARM example submitted to the Sparkfun web site by Jim Parise.

```
11
11
      HARDWARE INTERFACE
11
11
        . . . . . . . . . . . . . . . .
11
11
      The Nokia 6610 display uses a SPI serial interface (9 bits)
11
11
             PA2 = LCD Reset (set to low to reset)
             PA12 = LCD chip select (set to low to select the LCD chip)
11
11
             PA16 = SPI0 MISO Master In - Slave Out (not used in Olimex SAM7-EX256 LCD interface)
             PA17 = SPI0_MOSI Master Out - Slave In pin (Serial Data to LCD slave)
11
             PA18 = SPI0 SPCK Serial Clock (to LCD slave)
11
11
             SPI baud rate set to MCK/2 = 48054841/8 = 6006855 baud
11
             (period = 166 nsec, OK since 150 nsec period is min for PCF8833)
11
11
       The important thing to note is that you CANNOT read from the LCD!
11

               The best way to fill a rectangle is to take advantage of the "wrap-around" featute
11
               built into the Philips PCF8833 controller. By defining a drawing box, the memory can
11
               be simply filled by successive memory writes until all pixels have been illuminated.
11
11
                      1. Given the coordinates of two opposing corners (x0, y0) (x1, y1)
11
11
                           calculate the minimums and maximums of the coordinates
11
11
                              xmin = (x0 \le x1) ? x0 : x1;
                              xmax = (x0 > x1) ? x0 : x1;
11
                              ymin = (y0 <= y1) ? y0 : y1;</pre>
11
                              ymax = (y0 > y1) ? y0 : y1;
11
11
```

```
2. Now set up the drawing box to be the desired rectangle
11
11
11
                             WriteSpiCommand(PASET);
                                                                 // set the row boundaries
                             WriteSpiData(xmin);
11
                             WriteSpiData(xmax);
11
11
                             WriteSpiCommand(CASET);
                                                                 // set the column boundaries
                             WriteSpiData(ymin);
11
11
                             WriteSpiData(ymax);
11
                      3. Calculate the number of pixels to be written divided by 2
11
11
11
                             NumPixels = ((((xmax - xmin + 1) * (ymax - ymin + 1)) / 2) + 1)
11
                             You may notice that I added one pixel to the formula.
11
                             This covers the case where the number of pixels is odd and we
11
                             would lose one pixel due to rounding error. In the case of
11
                             odd pixels, the number of pixels is exact.
//
                             in the case of even pixels, we have one more pixel than
11
11
                             needed, but it cannot be displayed because it is outside
11
                             the drawing box.
11
11
                             We divide by 2 because two pixels are represented by three bytes.
11
                             So we work through the rectangle two pixels at a time.
11
                      4. Now a simple memory write loop will fill the rectangle
11
11
11
                             for (i = 0; i < ((((xmax - xmin + 1) * (ymax - ymin + 1)) / 2) + 1); i++) {
                                    WriteSpiData((color >> 4) & 0xFF);
11
11
                                     WriteSpiData(((color & 0xF) << 4) | ((color >> 8) & 0xF));
                                     WriteSpiData(color & 0xFF);
11
                             }
11
11
              In the case of an unfilled rectangle, drawing four lines with the Bresenham line
11
              drawing algorithm is reasonably efficient.

11	>
11	
11	
	(20,20) (20,27)
11	
11	The most efficient way to display a character is to make use of the "wrap-around" feature of the Philips PCF8833 LCD controller chip.
// //	Assume that we position the character at (20, 20) that's a (row, col) specification.
11	With the row and column address set commands, you can specify an 8x8 box for the SMALL and MEDIUM characters or a 16x8 box for the LARGE characters.
11	
11	WriteSpiCommand(PASET); // set the row drawing limits
11	WriteSpiData(20); // WriteSpiData(27); // limit rows to (20, 27)
// //	
11	WriteSpiCommand(CASET); // set the column drawing limits
// //	WriteSpiData(20); // WriteSpiData(27); // limit columns to (20,27)
11	
11	When the algorithm completes col 27, the column address wraps back to 20
11	At the same time, the row address increases by one (this is done by the controller)
11	We walk through each row, two pixels at a time. The purpose is to create three
11	data bytes representing these two pixels in the following format (as specified by Philips for RGB 4 : 4 : 4 format (see page 62 of PCF8833 controller manual).
// //	Data for pixel 0: RRRRGGGGBBBB
 	Data for Pixel 1: RRRRGGGBBBB
11	WriteSpiCommand(RAMWR); // start a memory write (96 data bytes to follow)
11	WriteSpiData(RRRGGGG); // first pixel, red and green data
// //	WriteSpiData(BBBBRRRR); // first pixel, blue data; second pixel, red data WriteSpiData(GGGBBBB); // second pixel, green and blue data
11	
// //	and so on until all pixels displayed!
// //	WriteSpiCommand(NOP); // this will terminate the RAMWR command
11

### LCD.C (for Epson S1D15G00 Controller only)

The **Icd.c** module contains the SPI support code and a complete set of LCD graphics primitives. The line drawing and circle routines are derived from the famous Jack Bresenham algorithms from 1962. The rest of the graphics primitives are designed by the author. The font tables were adapted from the ARM example submitted to the Sparkfun web site by Jim Parise.

11
11
11
          Draws a rectangle in the specified color from (x1,y1) to (x2,y2)
11
          Rectangle can be filled with a color if desired
11 11 11
                                  row address (0 .. 131)
column address (0 .. 131)
0=no fill, 1-fill entire rectangle
          Inputs:
                      х
                             =
                            =
                      У
                      fill =
                                  12-bit color value for lines rrrrggggbbbb
rrrr = 1111 full red
11
                      color =
ii
ii
                                        0000 red is off
...
||
||
                                        gggg = 1111 full green
11
11
                                        0000 green is off
11
                                        bbbb = 1111 full blue
                                        0000 blue is off
11
11
             Returns: nothing
11
11
          Notes:
11
11
          The best way to fill a rectangle is to take advantage of the "wrap-around" featute
11111
          built into the Epson S1D15G00 controller. By defining a drawing box, the memory can be simply filled by successive memory writes until all pixels have been illuminated.
          1. Given the coordinates of two opposing corners (x0, y0) (x1, y1)
||
||
               calculate the minimums and maximums of the coordinates
||
||
                    xmin = (x0 <= x1) ? x0 : x1;
xmax = (x0 > x1) ? x0 : x1;
ymin = (y0 <= y1) ? y0 : y1;</pre>
11
11
                    ymax = (y0 > y1) ? y0 : y1;
11
11111
          2. Now set up the drawing box to be the desired rectangle
                    WriteSpiCommand(PASET);
                                                            // set the row boundaries
                    WriteSpiData(xmin);
11
                    WriteSpiData(xmax);
                    WriteSpiCommand(CASET);
                                                            // set the column boundaries
                    WriteSpiData(ymin);
//
11
                    WriteSpiData(ymax);
11
```

```
3. Calculate the number of pixels to be written divided by 2
11
...
||
||
                      NumPixels = ((((xmax - xmin + 1) * (ymax - ymin + 1)) / 2) + 1)
11
11
                      You may notice that I added one pixel to the formula.
                     This covers the case where the number of pixels is odd and we
would lose one pixel due to rounding error. In the case of
odd pixels, the number of pixels is exact.
11
11
                      in the case of even pixels, we have one more pixel than
                      needed, but it cannot be displayed because it is outside
11
                      the drawing box.
11
                      We divide by 2 because two pixels are represented by three bytes.
11
                      So we work through the rectangle two pixels at a time.
||
||
||
           4. Now a simple memory write loop will fill the rectangle
                     for (i = 0; i < ((((xmax - xmin + 1) * (ymax - ymin + 1)) / 2) + 1); i++) {
    WriteSpiData((color >> 4) & 0xFF);
    WriteSpiData(((color & 0xF) << 4) | ((color >> 8) & 0xF));

//
//
                                WriteSpiData(color & 0xFF);
11
                     }
11
11
           In the case of an unfilled rectangle, drawing four lines with the Bresenham line
11
           drawing algorithm is reasonably efficient.

11 The most efficient way to display a character is to make use of the "wrap-around" feature of the Epson S1D16G00 LCD controller chip. ... || || 11 11 Assume that we position the character at (20, 20) that's a (row, col) specification. With the row and column address set commands, you can specify an 8x8 box for the SMALL and MEDIUM || || characters or a 16x8 box for the LARGE characters. 11 WriteSpiCommand(PASET); // set the row drawing limits WriteSpiData(20); // limit rows to (20, 27) 11 WriteSpiData(27); 11 11 11 11 WriteSpiCommand(CASET); // set the column drawing limits WriteSpiData(20); // limit columns to (20,27) WriteSpiData(27); When the algorithm completes col 27, the column address wraps back to 20 At the same time, the row address increases by one (this is done by the controller) We walk through each row, two pixels at a time. The purpose is to create three // // data bytes representing these two pixels in the following format 11 Data for pixel 0: RRRRGGGGBBBB 11 11 11 Data for Pixel 1: RRRRGGGGBBBB // start a memory write (96 data bytes to follow) WriteSpiCommand(RAMWR); 11 11 11 WriteSpiData(RRRRGGGG); // first pixel, red and green data
// first pixel, blue data; second pixel, red data
// second pixel, green and blue data WriteSpiData(BBBBRRRR); WriteSpiData(GGGGBBBBB); // 11 and so on until all pixels displayed! 11 // this will terminate the RAMWR command 11 WriteSpiCommand(NOP); 11 11 11 Author: James P Lynch August 30, 2007 11 void LCDPutChar(char c, int x, int y, int size, int fColor, int bColor) { extern const unsigned char FONT6x8[97][8]; extern const unsigned char FONT8x8[97][8]; extern const unsigned char FONT8x16[97][16]; int i,j; unsigned int nCols; unsigned int nRows; unsigned int nBytes; unsigned char PixelRow; unsigned char Mask; unsigned int Word0: unsigned int Word1; unsigned char \*pFont; unsigned char \*pChar; unsigned char // get pointer to the beginning of the selected font table pFont = (unsigned char \*)FontTable[size]; // get the nColumns, nRows and nBytes nCols = \*pFont; nRows = \*(pFont + 1); nBytes = \*(pFont + 2); // get pointer to the last byte of the desired character

### Sample Main Program Test Routine

The following is a simple main program that exercises every one of the LCD graphics primitives. It works with the driver code for either the Philips controller or the Epson controller. After the tests have been completed, the main program falls into an endless blink loop. Since the SAM7-EX256 board has no user-programmable LED, the author added one as shown in the program's annotation (you could remove the LED code if you like).

11 11 main.c 11 Nokia 6610 LCD demonstration program for Olimex SAM7-EX256 Evaluation Board 11 11 Performs a series of tests of the LCD driver. 11 11 When tests are complete, blinks LED4 (pin PA3) with an endless loop 11 11 PA3 is pin 1 on the EXT 20-pin connector (3.3v is pin 18) 11 11 The Olimex SAM7-EX256 board has no programmable LEDs. Added a simple test LED from Radio Shack as shown below (attached to the 20-pin EXT connector.) 11 11 11 3.3 volts |-----| anode |----| PA3 EXT 0----- 470 ohm ----- LED ------ 0 EXT 11 Pin 18 |-----| 11 |----| cathode pin 1 Radio Shack Red LED 11 276-026 T-1 size (anode is the longer wire) 11 11 LED current: I = E/R = 3.3/470 = .007 amps = 7 ma 11 Note: most PIO pins can drive 8 ma on the AT91SAM7X256, so we're OK 11 11 11 11 Author: James P Lynch July 7, 2007 11 11 11 Header Files 11 #include "AT91SAM7X256.h" #include "lcd.h"
#include "board.h" 11 External References 11 extern void LowLevelInit(void); int main (void) { unsigned long j; unsigned long k; unsigned long col; unsigned long row; unsigned int IdleCount = 0; TempColor[11] = { WHITE, BLACK, RED, GREEN, BLUE, CYAN, MAGENTA, YELLOW, BROWN, ORANGE, PINK }; int char // Initialize the Atmel AT91SAM7S256 (watchdog, PLL clock, default interrupts, etc.) LowLevelInit(); // Set up the LED (PA3) volatile AT91PS\_PI0 pPI0 = AT91C\_BASE\_PI0A; // pointer to PI0 data structure // PIO Enable Register - allow PIO to control pin PP3 pPIO->PIO\_PER = LED\_MASK; // PIO Output Enable Register - sets pin P3 to outputs pPIO->PIO\_OER = LED\_MASK; pPIO->PIO SODR = LED MASK; // PIO Set Output Data Register - turns off the LED

```
// Initialize SPI interface to LCD
InitSpi();
// Init LCD
InitLcd();
// clear the screen
LCDClearScreen();
// * color test - show boxes of different colors
for (j = 0; j < 11; j++) {
        // draw a filled box
        LCDSetRect(120, 10, 25, 120, FILL, TempColor[j]);
       // label the color
LCDPutStr(" ", 5, 40, LARGE, BLACK, BLACK);
LCDPutStr(TempChar[j], 5, 40, LARGE, YELLOW, BLACK);
        // wait a bit
       Delay(2000000);
}
// * character and line tests - draw lines, strings, etc.
// clear the screen

// draw some lines
LCDSetLine(120, 10, 120, 50, YELLOW);
LCDSetLine(120, 50, 80, 50, YELLOW);
LCDSetLine(80, 50, 80, 10, YELLOW);
LCDSetLine(80, 10, 120, 10, YELLOW);
LCDSetLine(120, 85, 80, 105, YELLOW);
LCDSetLine(80, 85, 120, 105, YELLOW);
// draw a circle
LCDSetCircle(65, 100, 10, RED);
Delay(8000000);
```

```
// *****
                 // * bmp display test - display the Olimex photograph
      // *******
      LCDClearScreen();
      LCDWrite130x130bmp();
      LCDPutStr("This guy is nuts", 115, 2, LARGE, BLACK, CYAN);
      // draw a filled box
      LCDSetRect(90, 70, 75, 120, FILL, YELLOW);
      LCDPutStr("HELP!", 80, 80, SMALL, BLACK, YELLOW);
      // * endless blink loop
      // ***
           *****
      while (1) {
            if ((pPIO->PIO ODSR & LED4) == LED4)
                                                   // read previous state of LED4
                   pPIO->PIO_CODR = LED4;
                                                   // turn LED4 (DS1) on
            else
                   pPIO->PIO SODR = LED4;
                                                   // turn LED4 (DS1) off
            for (j = 1000000; j != 0; j--);
                                                   // wait 1 second 1000000
            IdleCount++;
                                                   // count # of times through the idle loop
      }
}
```

When the main program runs, a series of color filled rectangles is displayed with the name of the color annotated at the bottom of the screen, as shown in Figure 13 below. The colors displayed are:

#### "White", "Black", "Red", "Green", "Blue", "Cyan", "Magenta", "Yellow", "Brown", "Orange", "Pink"

If you are curious as to how I developed my color values, I referred to this web site:

#### http://web.njit.edu/~kevin/rgb.txt.html

In this web site, **RGB to Color Name Mapping (Triplet and Hex)**, there is a decimal color table where each color value is in the range 0 to 255. I simply used proportionality to convert these values to a range of 0 to 15. This may come in handy when you need to display the color Turquoise!

Figure 13. Filled Rectangle

Figure 14. Text and Graphics

In Figure 14 above, the display shows various rectangles (filled and unfilled), lines and circles. The three font sizes are demonstrated and you can see some single pixel specifications on the far right.

In Figure 15 below, the Olimex BMP image has been displayed with a few overlays of text. Olimex has a free utility on their web site to convert pictures (.jpeg) into the 132 x 132 motif required by the Nokia 6100 LCD display. The text overlays demonstrate foreground and background color specification.

Figure 15. Display of a .bmp image with text

There is available with this tutorial two sample Eclipse projects; one for the Philips controller and one for the Epson controller. They are almost identical, save for the list of command codes in the file "lcd.h" and the InitLcd() routine in the file "lcd.c". You need only determine your controller type and then pick the appropriate example to use.

# Conclusions

I set out to write a Nokia 6100 LCD Display Driver that was 100% related to the Philips and Epson Data Sheets. I generally succeeded but there is still the mystery of why the display needed to be inverted and the RGB setting had to be reversed. The subroutines contained herein are the most efficient for this particular controller.

If you need to port this to a different computational platform, then you need to modify the port pins used and rewrite the SPI routines to conform to the alternate microprocessor. I suspect most people could easily handle such details.

I would appreciate comments on this work and would be happy to accept any suggested improvements for inclusion in a future release.

## About the Author

Jim Lynch lives in Grand Island, New York and is a software developer for Control Techniques, a subsidiary of Emerson Electric. He develops embedded software for the company's industrial drives (high power motor controllers) which are sold all over the world.

Mr. Lynch has previously worked for Mennen Medical, Calspan Corporation and the Boeing Company. He has a BSEE from Ohio University and a MSEE from State University of New York at Buffalo. Jim is a single Father and has two grown children who now live in Florida and Nevada. He has two brothers, one is a Viet Nam veteran in Hollywood, Florida and the other is the Bishop of St. Petersburg, also in Florida. Jim plays the guitar (search for lynchzilla on youtube.com), enjoys woodworking and hopes to write a book very soon that will teach students and hobbyists how to use these high-powered ARM microcontrollers. Lynch can be reached via e-mail at: lynch007@gmail.com
